

QED Feynman Rules in the Counterterm Perturbation Theory

The simplest version of QED (Quantum ElectroDynamics) has only 2 field types — the electromagnetic field A^μ and the electron field Ψ — and its physical Lagrangian is

$$\mathcal{L}_{\text{phys}} = -\frac{1}{4}F_{\mu\nu}F^{\mu\nu} + \bar{\Psi}(i\gamma^\mu D_\mu - m_e)\Psi = -\frac{1}{4}F_{\mu\nu}^2 + \bar{\Psi}(i\partial - m)\Psi + eA_\mu\bar{\Psi}\gamma^\mu\Psi. \quad (1)$$

The bare Lagrangian of the perturbation theory has a similar form, except for the bare coupling e_{bare} instead of the physical coupling e , the bare electron mass m_{bare} instead of the physical mass m , and the bare fields $A_{\text{bare}}^\mu(x)$ and $\Psi_{\text{bare}}(x)$ instead of the renormalized fields $A^\mu(x)$ and $\Psi(x)$. By convention, the fields strength² factors Z for the EM and the electron fields are called respectively the Z_3 and the Z_2 , while the Z_1 is the electric charge renormalization factor. Thus,

$$A_{\text{bare}}^\mu(x) = \sqrt{Z_3} \times A^\mu(x), \quad \Psi_{\text{bare}}(x) = \sqrt{Z_2} \times \Psi(x), \quad (2)$$

and plugging these bare fields into the bare Lagrangian we obtain

$$\mathcal{L}_{\text{bare}} = -\frac{Z_3}{4}F_{\mu\nu}F^{\mu\nu} + Z_2\bar{\Psi}(i\partial - m_{\text{bare}})\Psi + Z_1e \times A_\mu\bar{\Psi}\gamma^\mu\Psi \quad (3)$$

where

$$Z_1 \times e = Z_2\sqrt{Z_3} \times e_{\text{bare}} \quad (4)$$

by definition of the Z_1 .

As usual in the counterterm perturbation theory, we split

$$\mathcal{L}_{\text{bare}} = \mathcal{L}_{\text{phys}} + \mathcal{L}_{\text{terms}}^{\text{counter}} \quad (5)$$

where the physical Lagrangian $\mathcal{L}_{\text{phys}}$ is exactly as in eq. (1) while the counterterms comprise the difference. Specifically,

$$\mathcal{L}_{\text{terms}}^{\text{counter}} = -\frac{\delta_3}{4} \times F_{\mu\nu}F^{\mu\nu} + \delta_2 \times \bar{\Psi}i\partial\Psi - \delta_m \times \bar{\Psi}\Psi + e\delta_1 \times A_\mu\bar{\Psi}\gamma^\mu\Psi \quad (6)$$

for

$$\delta_3 = Z_3 - 1, \quad \delta_2 = Z_2 - 1, \quad \delta_1 = Z_1 - 1, \quad \delta_m = Z_2m_{\text{bare}} - m_{\text{phys}}. \quad (7)$$

Actually, the bare Lagrangian (5) is not the whole story, since in the quantum theory

- The physical vertex

$$= (+ie\gamma^\mu)_{\alpha\beta}. \quad (14)$$

The Dirac indices α and β of the fermionic lines are usually not written down.

- ★ And then there are three kinds of the counterterm vertices:

$$= +ie\delta_1 \times (\gamma^\mu)_{\alpha\beta}, \quad (15)$$

$$= +i(\delta_2 \times \not{p} - \delta_m)_{\alpha\beta}, \quad (16)$$

$$= -i\delta_3 \times (g^{\mu\nu} k^2 - k^\mu k^\nu). \quad (17)$$
